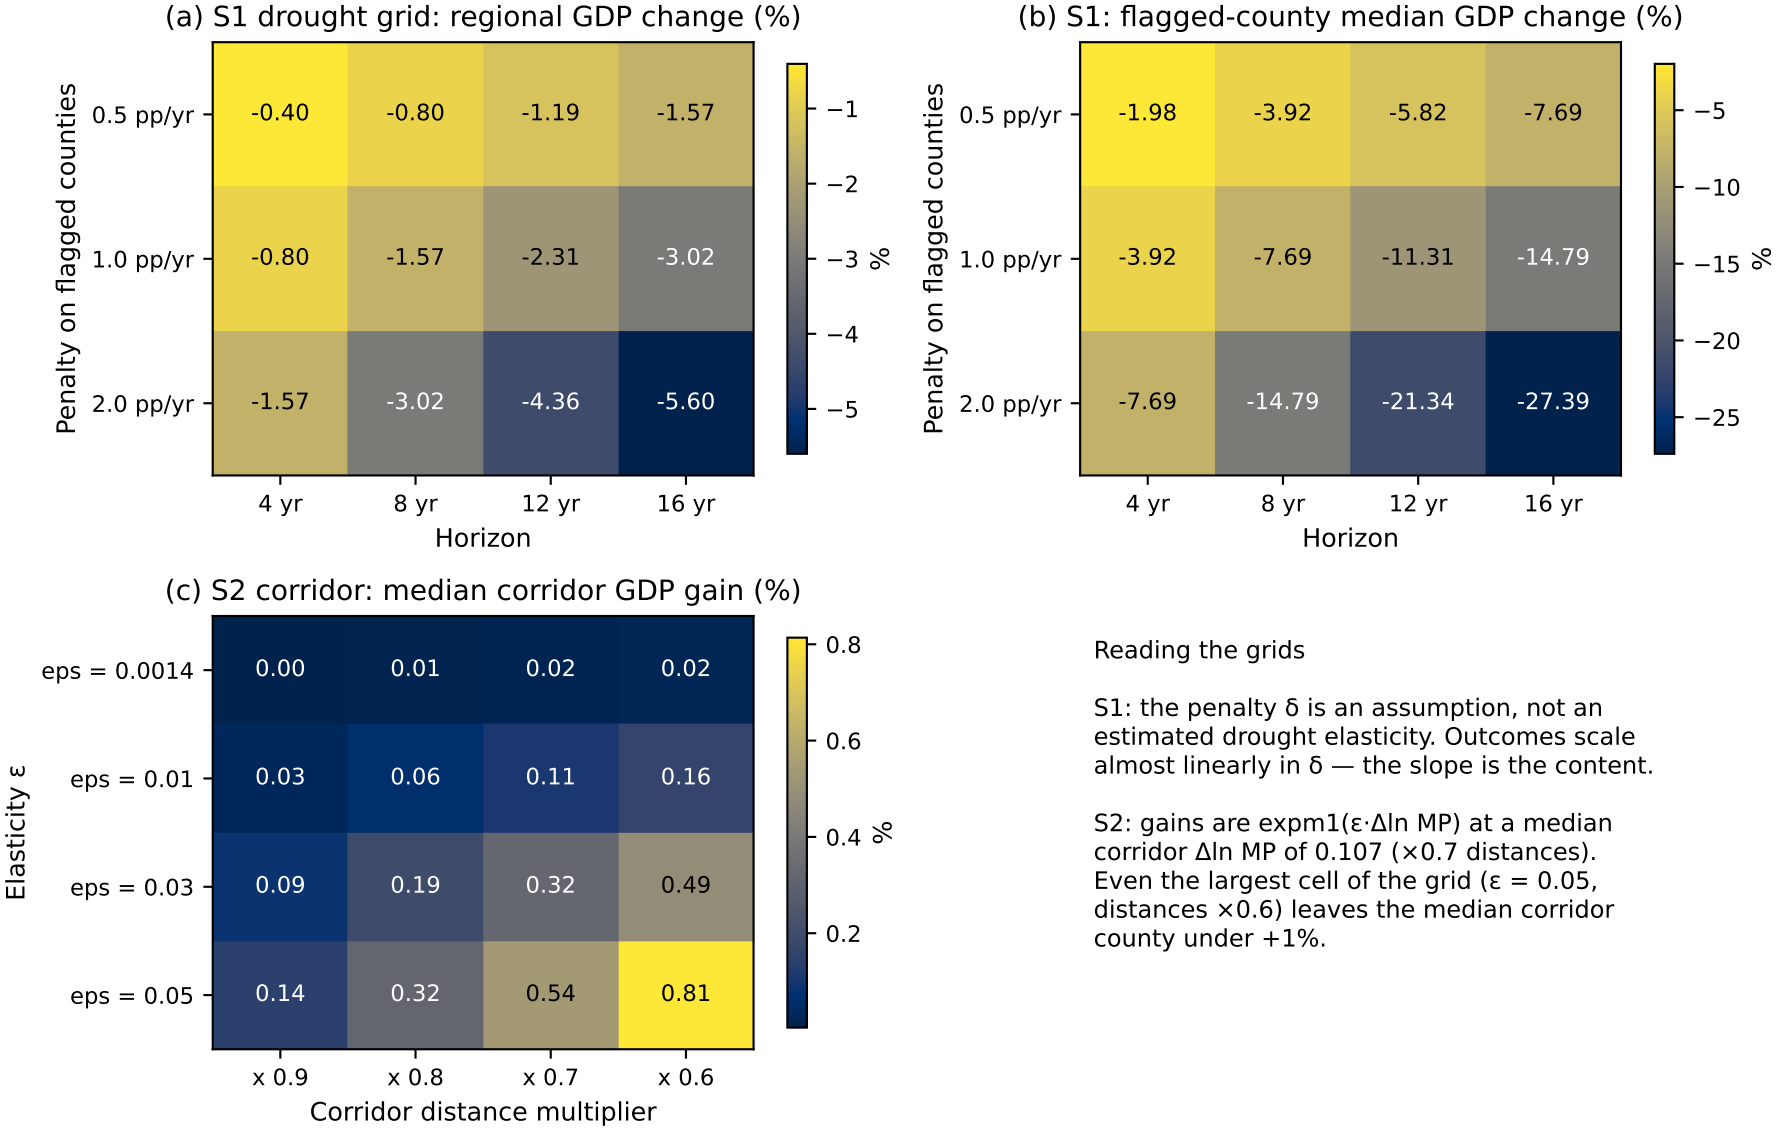
Figure 4. Scenario sensitivity grids — SIMULATION OUTPUT, not forecasts



Reading the grids

S1: the penalty δ is an assumption, not an estimated drought elasticity. Outcomes scale almost linearly in δ — the slope is the content.

S2: gains are expm1(ε·Δln MP) at a median corridor Δln MP of 0.107 (×0.7 distances). Even the largest cell of the grid (ε = 0.05, distances ×0.6) leaves the median corridor county under +1%.

Source: author's calculations; assumptions as stated in Section 5.
